Plant Ecology and Evolution

Why are some species able to cope with environmental changes?

How have organisms responded to environmental change in the past? We are interested in how plant species cope with and even adapt to environmental changes such as climate change and land use.

We conduct research using field surveys, common garden experiments, diversity manipulation experiments, ecological genomics, and ecological niche modeling, with a particular focus on sources of genetic diversity that enable rapid evolutionary responses and mechanisms of population maintenance through interactions among organisms.

Applied Ecology

In the last few decades, biodiversity loss has been a big issue all over the world. As you know, human activities are one of the most primary factors, which modify the natural habitats of animal and plant species, cause the decline of their population, and sometimes completely make them extinct. To live as a well-behaved passenger on the future earth, we first need to understand the relationship between biodiversity and human activities. In our laboratory, we study for and actually perform for conservation and appropriate management of biodiversity. And, we believe these should be done based on accurate knowledge about biology, ecology, and environmental science. We are targeting various taxa, such as endangered fishes, invasive crustaceans, and native herbaceous plants.

Soil Management

Agriculture is responsible for emissions of greenhouse gases (GHGs) such as carbon dioxide (CO₂), nitrous oxide (N₂O), and methane (CH₄). Production of these gases in farmland soil results from biological processes like organic matter decomposition, nitrification and denitrification, and highly depends on organic matter inputs. We aim at analyzing the effects of organic matter amendment on GHGs emissions. In particular, we are interested in agricultural soil amended with livestock compost.

Prof. MAEDA Morihiko

 Nutrient dynamics in soil-plant
 ecosystems

Conservation of Aquatic Biodiversity

Molluscs including shellfish, snails, slugs and so on are a very diversified animal group and consist of more than 80,000 Recent species in the world, but their taxonomy and recognition of species are still poorly understood. For example, *Turbo sazae* is one of the most well-known marine snails in Japan since ancient age, but nevertheless the species has long been misidentified with *Turbo cornutus*, a species endemic to China, until recently and documented to be unnamed in 2017. Another edible species *Tegula kusairo* exhibited the similar case and it was described as a new species in 2020. Furthermore, many species become extinct or critically endangered by artificial environmental changes before recognizing their presences by human beings. The alpha-taxonomy of this group is thus highly important and an urgent matter in terms of biodiversity conservation.

Food and Environmental Policy

Toward the "Asian Ways" of Sustainable Development: Viewing Our Food and Environment from Social, Political, and Economic Perspectives
Social sciences and humanities (SSH) can contribute to solving food and environmental problems. We are especially employing area studies/political and economic perspectives to broadly re-examine these issues in Asia, such as agriculture, resource industries, environmental policies, community-based development, disaster management, etc. The 21st century is believed to be the Asian century. The future of our world thus largely rests on how Asia commits to sustainability. Based on domestic, foreign, and international research from Asia and other regions, we wish to examine changes in human-nature relationships and the balance between development and the environment.

 Food Chemical Biology (Biological and physiological functions of food phytochemicals)/Functional Mechanism and Bioavailability of Food Factors

Chemistry of Bio-signalling

In particular, our research focuses on stress signaling regulating stomatal movement. Stomatal pores, which are formed by pairs of guard cells in the epidermis especially of leaves, regulate gas exchange for photosynthesis and transpirational water loss. Guard cells can perceive various stimuli such as light, CO₂, pathogen infection, and various phytohormones such as abscisic acid, then transducing the inputs to a change in stomatal aperture. Using multidisciplinary approaches, we aim to reveal the detailed mechanisms of signaling cascading from stress sensing to stomatal aperture regulation in guard cells. We also study the basic mechanisms of heavy metal and salt stress responses in plants using model plants as well as cultured cells. Our research advance will contribute to develop new technologies that improve crop productivity and safety.

Plant Genetics and Physiology

Our life on earth cannot continue without the atmospheric environment, which is maintained by oxygenic photosynthesis. Plants perform photosynthesis in chloroplasts, where light energy is converted into chemical energy by a series of electrochemical reactions. In contrast, land plants are exposed incessantly to excess light energy or harsh atmospheric environments that engender 'photodamage'. How do plants cope with such photosynthetic inactivation? What are the key elements to maintaining or even maximizing chloroplast functions? Our group studies various aspects of chloroplast development and photosynthesis. By understanding the factors involved in photoprotection and chloroplast function, we aim to improve crop productivity against atmospheric stress over the long term.

Signaling Mechanisms

Did you know that plants, despite being rooted in one spot, are actually quite adaptable to changes in their environment? It's fascinating to think about how they sense and respond to these changes without having a nervous system or brain like animals do. This is a question that scientists are still trying to answer. Our research group is specifically investigating how plants integrate and analyze environmental information, even at the tissue level, to determine the best response as individuals. We're focusing on plant hormone responses and chromatin regulation, using techniques like physiological and molecular biology, as well as molecular genetics. Our ultimate goal is to apply this knowledge to develop stress-tolerant crops that can thrive even in challenging conditions. By understanding how plants handle environmental stress, we can help create a more sustainable and resilient food supply for the future.

Molecular Virology

Plant growth is influenced by various microorganisms including both beneficial and harmful ones. Among them are plant-infecting viruses that cause serious damage to crops and mycoviruses infecting phytopathogenic fungi that serve as biocontrol (virocontrol agents). Also, an increasing number of bacteria and fungi mutualistic to plants that enhance plant growth and stress tolerance. This group is mainly engaged in the three projects below.

Plant-Insect Interactions

Establishment of effective plant defense systems against herbivores in natural history reflects the existence of extremely variable interactions between plants and insects, also known as co-evolution process. Our group strives to understand, at a molecular level, the mechanisms of activation, signal transduction and metabolic basics of plant defenses triggered after the recognition of insect attack. Furthermore, we target sustainable pest control by the use of natural enemies and their attraction to herbivore-infested plants by the emissions of various volatile organic compounds (VOCs) from plants.

Plant-Environmental Microbiology

By understanding the ecology of Methylobacterium species, which utilize methanol released by plants and dominate on leaves, we will apply their function as growth-promoting bacteria to agriculture. We are also analyzing the rhizosphere microbial community structure in crop ecosystems. On the other hand, we are trying to uncover the mechanism of growth and mortality of bloom-forming phytoplankton, which cause damage to fisheries, by focusing on symbiotic bacteria.

Plant-Pathogen Interactions

Rice is the world's most important crop, and improving rice is an important research challenge.

Our ultimate goal is to design new rice varieties that exhibit resilience against abiotic stresses while augmenting essential agronomic traits. To achieve this ambitious goal, we investigate immunoreceptors and the small G protein OsRac 1, both of which play pivotal roles in rice immunity. We firmly believe that we can successfully engineer a robust rice immune system by acquiring a comprehensive understanding of the functions performed by immunoreceptors and OsRac 1.

Plant Functional Genomics

Barley, the fourth most important cereal crop in the world, typically has seeds with adhered hulls. This hulled seed trait is suitable for breweries. Some naked seed mutants with easily separable hulls were generated through spontaneous mutation. They are suitable for food usage. We have revealed that barley awns and spike hulls are photosynthetically active. Our current research specifically examines molecular identification and characterization of beneficial genes controlling (1) seed morphology and quality, including water soluble healthy dietary fiber, and (2) photosynthetic contribution of awns and hulls by using mutants. We seek application of our basic findings to practical breeding.

Plant Diversity Analysis

We conserve and evaluate barley genetic resources (varieties and lines) collected from all over the world. These genetic resources vary in characteristics depending on the location of collection and purpose of use, for example, there are regional differences in vernalization requirements (the degree of low-temperature exposure required for flowering).

Based on our evaluation of genetic resources, we carry out genetic analysis, gene isolation, and functional analysis of stress tolerance, such as grain dormancy and disease resistance, for application use.

Integrated Genomic Breeding

Exploring and utilization of useful traits from diverse rice genetic resources
Rice is cultivated all around the world and shows numerous morphological and physiological differences in the form of phenotypic variations. Some of these variations have been used as genetic resources to improve rice plants so that they better satisfy human needs. Phenotypic variations are considered to be genetically controlled by the collective function of a large number of genes on rice genomes. However, the genetic bases and biological functions of most of them are still unknown, which has prevented us from wider practical application of rice germplasms. We exploit useful phenotypic variations from a wide range of rice germplasms and clarify the genes involved with biological functions by aid of recent advances in genome information and technology. Also, we try to develop new breeding materials and propose more effective breeding methodologies.

Plant Genome Dynamics Analysis

Our laboratory conducts genetic and breeding research on sweetpotato. Using a Next Generation Sequencer (hereinafter referred to as NGS) that outputs a huge amount of DNA sequence data, we are working on the development of DNA markers and gene identification related to important agricultural traits such as disease and pest resistance and yield. We are also conducting gene expression analysis (Iso-Seq, RNA-seq analysis, etc.) to elucidate the mechanism of disease resistance, and also developing novel genotyping systems applicable to polyploid crop species.

Plant Pathology

The Food and Agriculture Organization (FAO) reports that over 850 million people face insufficient access to food, and an estimated 24,000 people succumb to hunger daily. Given that plant diseases cause annual yield losses of up to 20% in food and cash crops, continuous improvement and advancement of pest management systems is essential to sustainably feed a growing world population. To achieve this goal, we focus on elucidating the molecular mechanisms that govern plant immunity and pathogen virulence, and on innovating new technologies to control plant diseases.

Vegetable Crop Science

Investigation of physiological characteristics related to vegetable production and development of production systems

We are conducting research on vegetable production, such as tomatoes and strawberries, from the perspective of how the growing environment affects crop quality, yield and other agricultural traits. Recently, we especially focus on efficient environmental control in greenhouse cultivation and pollination control in strawberry production.

Another research theme is the use of the flowering hormone (florigen) in vegetable production and breeding. We are conducting basic research and developing technologies to efficiently deliver florigen using grafting for cruciferous vegetables such as cabbage and radish.

We are also carrying out various other studies on vegetables, such as the evaluation of quality characteristics of traditional vegetables, the development of efficient watering technology in cucumber cultivation, and the development of vapor pressure deficit (VPD) control methods in the cultivation of melons and eggplants.

Crop Science

Environmental destruction is progressing now at an unprecedented scale, in the form of global warming and accompanying desertification, salt accumulation in soil, depletion of water resources, and so on. On the other hand, the human population continues to increase, and there is strong demand for expansion of food production. Therefore, in addition to improving the grain yield in arable land suitable for

cultivation, production of agricultural crops is necessary even in inadequate lands affected by water shortage, salt accumulation etc. In this field we conduct physiological and ecological research and education concerning various crops for the purpose of improving crop production under defective environmental conditions.

Animal Breeding and Genetics

The aim of animal breeding and genetics is to investigate invisible genetic events using statistical and molecular genetics analysis. Then we can understand the genetic structure of a population and the genetic features of an animal, which is useful for designing an optimum breeding program. In particular, we are interested in genetic evaluation using genomic information and the genetic diversity in the animal population. Through our research activity, young scientists are encouraged to acquire the necessary knowledge and techniques to pursue scientific careers in quantitative genetics in the post-genome era.

$$Y = XH + Zs + \epsilon$$

$$\begin{bmatrix} X'X & X'Z \\ Z'X & Z'Z + A^{-1}\sigma_e^2/\sigma_s^2 \end{bmatrix} \begin{bmatrix} \hat{H} \\ \hat{s} \end{bmatrix} = \begin{bmatrix} X'Y \\ Z'Y \end{bmatrix}$$

Y: vector of observed phenotype.
 X, Z: known incidence matrices

Animal Applied Microbiology

It has become clear that gut microbiota (microflora) changes depending on the food components ingested by humans and their lifestyle, and that differences and changes in the microflora affect human health and disease. Morita group analyzes the gut microbiota of humans and animals, and tries elucidating the functions of the microbiota.

In Arakawa group, roles and application of beneficial microorganisms, mainly lactic acid bacteria, for processing and preservation of milk and egg products are researched. In particular, it is aimed to create novel safe and high quality milk and egg products using functional substances from and fermentation techniques with lactic acid bacteria.

In addition, both groups also carry out whole-genome analysis of intestinal bacteria, bifidobacteria and lactic acid bacteria radically to understand them.

Animal Nutrition

Microbiome research to gain insights into food, health, and environment relationships

- A healthy environment and healthy animals support food for humans
- Disease prevention and food hygiene require microbiome management
- Collaboration with tropical Asia to tackle food production under global warming

Nutrition is the study of a series of biological processes necessary for life. The goal of nutrition study is to improve human health and quality of life. Animal nutrition is a field that has been expanded to include animals. In our laboratory, we are doing research using a variety of animals, i.e., model animals, food-producing animals (livestock), wild animals, and companion animals. The research using model animals aims to clarify biochemical and physiological mechanisms associated with nutrition and metabolism. The members working on the projects use model animals and cultured cells for functional analyses of food. Several students work on food processing and its control. They are examining the characteristics of microorganisms involved in

fermentation to improve the safety and value of food and feed. Our goal is to solve problems in the industries, clarify the functions of food and feed, and achieve technological innovation related to nutrition, metabolism, and health.
